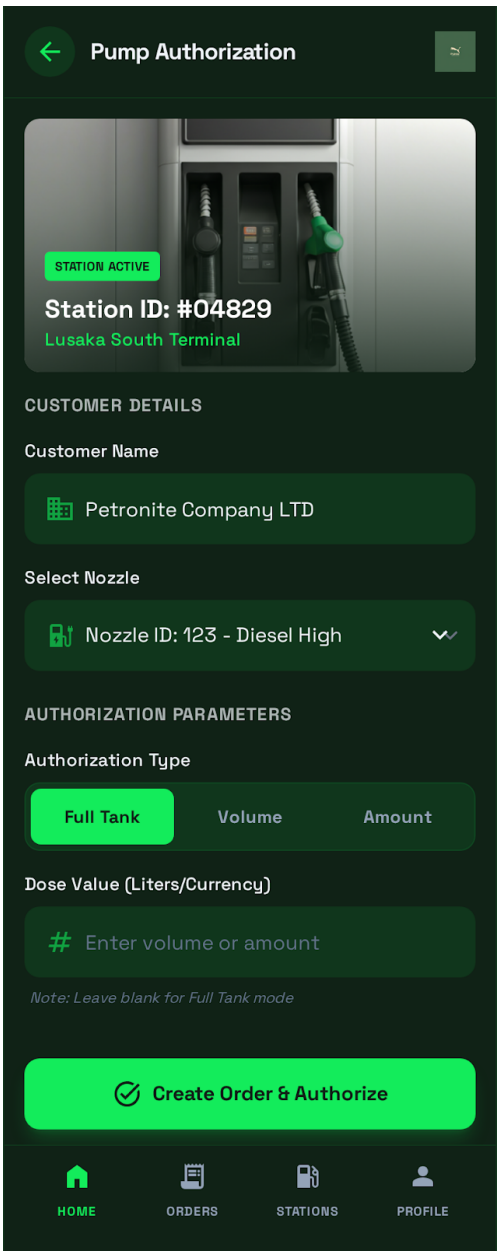
PROPOSED AUTHORIZAION FLOW

1. Lets assume customer with PUMA card arrives at the station for filling, you will probably have their card scanned to validate and do other stuff like balance checking or any check on your end
After you have successfully validated your customer you will redirect to a screen like this

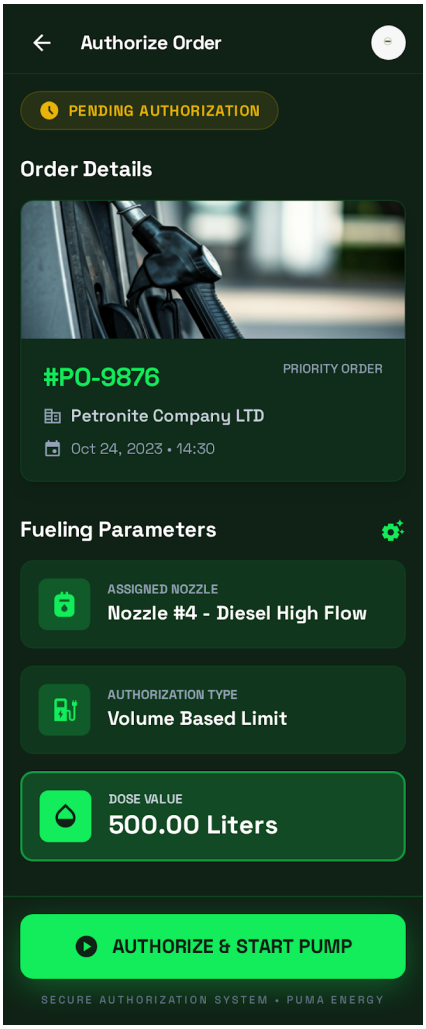


- To select Nozzle

- Select Authorization Type (There is api to fetch nozzles)

- If its Volume or Amount you should enter the Liters /Amount

2. Step is to Authorize a pump (This can be done from our App or you can also implement on your end there are api for this)



Why do we need two steps (Create Order and Authorize Order)?

The authorization process works in two stages to ensure proper control of the pump.

First, when an order is created, the pump is locked. This lock is necessary to distinguish between two types of authorization:

1. Normal Authorization – This happens automatically when the nozzle is lifted. In this case, the pump authorizes itself (From Petronite Command) without any intervention from the POS.
2. PUMA Authorization – This requires authorization from the POS system before fuel dispensing is allowed.

By locking the pump during order creation, we prevent the automatic authorization that normally occurs when the nozzle is lifted. Instead, the pump waits for the explicit authorization command from the POS.

Once the POS sends the authorization, the pump is then allowed to proceed with the transaction.

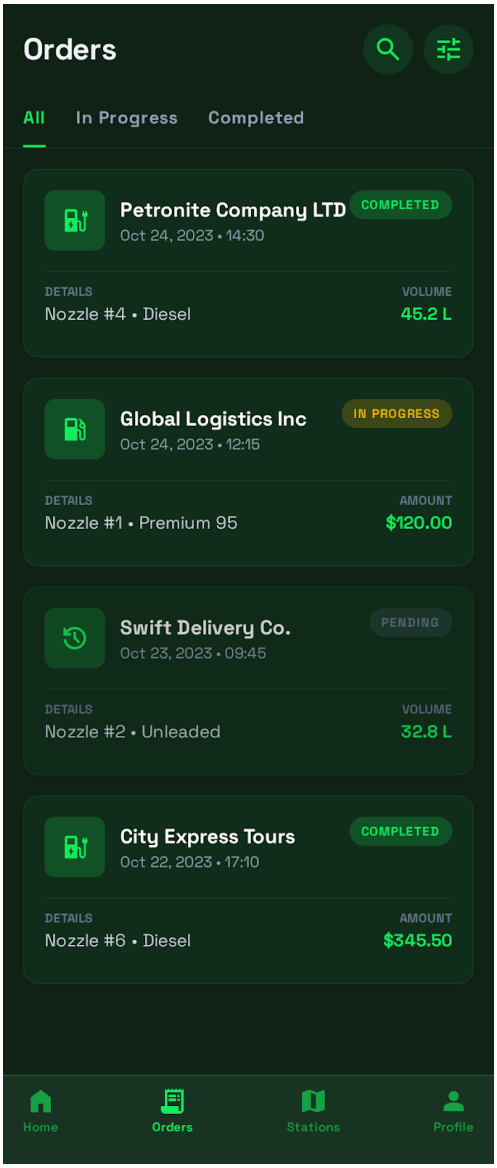
This two-step process ensures that the transaction is controlled by the POS system and avoids unintended automatic authorizations.

There is also an API to list pending orders.

In some situations, an attendant may create an order but accidentally exit the authorization screen, or leave the process before completing the authorization. In such cases, the order remains pending.

To handle this scenario, the system provides an API that allows the POS to retrieve all pending orders.

You may design a screen in the POS application that displays both pending and completed orders. This will allow the attendant to easily locate a pending order, select it, and continue with the authorization process.



Order Competion: After dispensing the fuel order will be completed automatically.
